**Background**

The LFSP Nutrition and Biofortification component aims to increase production and consumption of diverse, nutritious diets among target households. This objective is delivered through a well designed three pronged programming approach focusing on:

1. Support towards diversified crop and livestock production;
2. Promotion of biofortified crops and
3. Nutrition behaviour change communication targeting women of child bearing age and children under two years.

These three interventions are expected to directly lead to increased production of a wide variety of crops (including indigenous underutilized crops like millets) and livestock (particularly small livestock), increased production of biofortified crops – vitamin A maize (VAM) and high iron and zinc beans (HIB) and increased nutrition knowledge and understanding. This simultaneous attainment is expected to lead to increased consumption of diverse and nutritious foods which will in turn contribute towards improved household food and nutrition security of target households.

The LFSP is operational in 12 districts organised as follows:

<table>

Study Objective

The objective of the study was to assess how the LFSP Nutrition and Biofortification promotion activities are changing the targeted behaviours and practices of programme beneficiaries, with a view to identifying possible gaps, opportunities and further areas of focus moving forward.

Methodology

481 Households (HHs) sampled in 9 of the 12 LFSP districts
18 Focus Group Discussions with 107 farmers and 137 primary care givers participating in Care Groups
93 Key Informant Interviews (KII)

The study was conducted in 9 of the 12 LFSP Districts Mutare, Makoni, Mutasa, Bindura, Mt Darwin, Guruve, Kwekwe, Shurugwi and Gokwe South.

Summary Findings

Crop Production and Diversification

- The most commonly grown crops were white maize (89%), dark green vegetables (79%) and groundnuts (73%)
- Farmers also reported growing biofortified beans (55%), other beans (58%), orange coloured vegetables (65%), other sweet potatoes (54%) and orange maize (60%).
- The major source of SEED for white maize was the government input support programmes (62.9%). Including VAM and HIB into these schemes has potential to increase production
- Except for VAM (92.4) & HIB (95%) most HH (>50%) started growing the crops they grow before the LFSP.
- >40% hh reported starting to grow small grains and Irish potatoes after the programme.
- Decision to grow all crops was joint (male & females)>50%
- >65% of households reported household consumption as the major reason for growing all crops.

Summary Findings

Crop Production and Diversification

- The most commonly grown crops were white maize (89%), dark green vegetables (79%) and groundnuts (73%)
- Farmers also reported growing biofortified beans (55%), other beans (58%), orange coloured vegetables (65%), other sweet potatoes (54%) and orange maize (60%).

<td>17b (10.5)</td>
</tr>
</tbody>
</table>

Notes: *P < 0.05, Pearson’s Chi-square Test; †P value based on Fishers Exact Test

Growing of sorghum, rapoko, Irish potatoes, orange fleshed sweet potatoes, other sweet potatoes, NUA 45 beans and other fruits, was significantly associated with attainment of acceptable MDD-W by women aged 15-49 years in these households.

### Crop diversification

**KEY FINDINGS:**
- Growing of orange maize, Irish potatoes, and orange fleshed vegetables was significantly associated with attainment of acceptable MDD for children.
- Growing of sorghum, rapoko, Irish potatoes, orange fleshed sweet potatoes, other sweet potatoes, NUA 45 beans and other fruits, was significantly associated with attainment of acceptable MDD-W by women aged 15-49 years.
- Majority of households reported selling maize (50.7%) and dark green leafy vegetables (35%) on local markets, mostly from their households. Less than 35% of household reported selling crops like orange fleshed fruits and vegetables and small grains (with the exception of sorghum - 41%) on local markets.
- Majority of households still reported using traditional food preservation methods (direct solar drying - 96%, use of ordinary grain sacks – 46.2%), Lack of resources to acquire improved technologies was reported as a barrier. Low production also affected willingness to invest in preservation technologies.
- **Crop pests and diseases, high production costs and frequent droughts and water shortages** were reported as the major challenges faced in crop production by majority of farmers.

**KEY MESSAGES:**
- Farmers can produce more crops and in excess for sale on local markets if they are supported to overcome the challenges they are facing in crop production right now.
- Having excess produce sold on the local markets will help ensure those not able to produce can buy a wide variety of produce at relatively low prices locally. Only maize and green leafy vegetables are sold on local markets by majority of households.
- Growing crops like sorghum, rapoko, orange fleshed sweet potato, NUA45 beans and other fruits increases improves the chances of women and children consuming diets that meet their nutrient needs.
### Livestock Production

<table>

<td>27 (16.7)</td>
<td>0.004*</td>
</tr>
</tbody>
</table>

Notes: *P <0.05, Pearson’s Chi-square Test; †P value based on Fisher’s Exact Test

- Ownership of small livestock like sheep, rabbits and Boshveld chickens was significantly associated with attainment of acceptable MDD-W for women aged child bearing age (15-49 years) in these households. People keeping these small livestock were more likely to be consuming meat more than those not keeping these animals.
- Ownership of cattle was associated significantly with low MDD-W. FGD participants indicated that the primary reason for keeping the large livestock like cattle was for draught power and/or economic assets.

MDD - Minimum Dietary Diversity for Children. Indicator used to assess dietary diversity for children aged 6-23 months. Children consuming 4 of 7 food groups are said to be consuming a diet adequate to meet their nutrient needs for growth and development for an active healthy life.

MDD-W - Minimum Dietary Diversity for women. An indicator used to assess adequate dietary diversity for women aged 15-49 years. Women consuming 5 of 10 food groups are said to be eating a diet adequate to meet their nutrient acquirements for a healthy life.
Key Findings

- Cattle, goats and indigenous chickens were reportedly owned by majority of households. Other livestock owned included turkeys (15.2%), guinea fowls (15.8%) and boshveld chickens. Except for cattle, more than 50% of households reported starting to keep these livestock after they joined the programme.
- Unfortunately consumption of animal protein was at most once a week for the 1% of households with layers chickens and 1-2 time per months for majority of other small livestock.
- Only households that kept goats and indigenous chickens were associated with attainment of acceptable MDD for children.
- Ownership of small livestock like sheep, rabbits and Boshveld chickens (P=0.004) was significantly associated with attainment of acceptable MDD-W for women of child bearing age.
- Households keeping small livestock like goats, rabbits, indigenous and Boshveld chickens were more likely to consume meat than those not keeping these.
- Farmers reported joint ownership of majority of livestock they owned.
- Boshveld chickens (33%) and broiler chickens (6%) were the only livestock that farmers reported receiving support from the LFSP to own.
- Majority of the 4.6% owning broiler chickens and the 1% owning layers chickens reported that these were not for consumption, but for the market.
- Major challenges faced by farmers in livestock production were: livestock diseases and deaths, high production costs, lack of start-up capital and knowledge deficit. Farmers requested further support with animal health and disease management as well as access to improved livestock breeds.

Key messages

- Animal protein consumption by women and children was strongly correlated with household small livestock production, therefore strategies to enhance small livestock production particularly goats, indigenous and Boshveld chickens and chickens would significantly contribute to better household nutrition security.
Production of Biofortified crops

**Key Findings**

- Despite the high knowledge, production of biofortified crops remains relatively low 63% and 61% respectively.
- Farmers also reported growing just small portions for the VAM equivalent to 2kg seed at most compared to 10kg and more of white maize. Production was not enough to meet their day to day maize consumption.
- Majority of households reported getting VAM and HIB seed either from LFSP or other NGO programmes, 70% NGO for VAM and 80% LFSP for HIB.
- Cost of seed, late availability of seed in agrodealer shops as well as unavailability of seed at local levels were mentioned as some of the challenges affecting biofortified crop production
- Majority of HH reported willingness to buy VAM maize meal and HIB grain (95.8% AND 97.5% respectively).

**Key Message**

Production of VAM and HIB is still low, both in terms of proportion farmers growing - 63% and 61% respectively and level of production - mostly 2kg of seed or less for VAM and 1kg or less for HIB.

**NUTRITION BEHAVIOUR CHANGE COMMUNICATION (NBCC) USING THE CARE GROUP MODEL**

**Participation in Care Groups**

<table>
<thead>
<tr>

<td>90%</td>
</tr>
<tr>
<td>LFSP overall</td>
<td>63%</td>
</tr>
</tbody>
</table>

63.3% of eligible households (HH) had a member participating in the Care Groups.

**Key Findings**

- Participation in Care groups was very high in ENTERRPIZE followed by INSPIRE and very low in EXTRA.
- Care Group participants felt the behaviour change sessions were very helpful in increasing their knowledge and understanding of healthy eating and basic household hygiene.

## NBCC - USING THE CARE GROUP MODE

### Key Findings

- Knowledge of the promoted behaviours amongst Care Group participants was in all cases higher than practice.
- Participants mentioned several barriers affecting practice ranging from – poor access to food, influence of culture, lack of income to acquire promoted technologies, inadequate knowledge and confidence and general poverty.
- Many women however reported being motivated by ensuring good health and well being of their families.
- Women reported that they found the behaviour change sessions very helpful and participated willingly.

### Key messages

- Participation in Care Groups is still low and needs to be brought up to at least 80% of all eligible women and children for meaningful impact.
- Care groups should support women to overcome the barriers affecting their practice of the promoted behaviours.
Minimum Dietary Diversity for Women  MDD-W

### Key Findings

- Less women in LFSP districts were consuming diets adequate to meeting their nutritional needs compared to other places as reported by the ZimVAC 2019 Rural assessment report.
- The most commonly consumed food groups by women were fats and oils, other vegetables and cereals. Very few women reported consuming animal protein, legumes and orange coloured vegetable.

*Note: It is however worth noting the differences in the timing of the 2 assessments – the ZimVAC collected data just after the harvest – in April/May while the LFSP collected data at the start of the peak hunger season – in November 2019. Seasons have an effect on household food availability and can affect dietary diversity indicators.

### Key Messages

As highlighted in the findings under the crop section above, growing crops like sorghum, rapoko, HIB and fruits, together with small livestock like goats, indigenous chickens, Boshveld chickens and rabbits helps improve adequate nutrient intake for women and children. Supporting more households to achieve this is important to improve nutrition status of women and children in the LFSP.

CONSUMPTION OF DIVERSE AND NUTRITIOUS FOODS

Minimum Dietary Diversity for Children

Key Findings

• More children in LFSP districts were consuming diets adequate to meet their nutrition needs compared to many other children in the country as reported by various national assessments.

• Children of mothers and primary care givers participating in Care Groups were more likely to be consuming a minimum acceptable diet (53.4%) than their non-participating counterparts (35.8%).

• Unavailability of food in the households was reported by mothers and caregivers as the major reason for failing to feed children diverse diets – (Children are fed whatever is available in the household).

Key message

• The Care Group Model is helping improve children’s dietary patterns in LFSP districts.

Overall 45.3% of children in the sampled HHS were receiving the recommended minimum dietary diversity (MDD).
CONSUMPTION OF DIVERSE AND NUTRITION FOODS

Consumption of Biofortified Crops

Key findings

- Consumption of VAM in majority of LFSP districts was mostly just a few times per week, except in Gokwe South, Bindura, and Guruve where weekly consumption was reported.
- Households with a person participating in Care Groups reported more production and consumption of biofortified crops (77.8%), than those without (64.1%).
- Unlike maize, consumption of beans was a little more regular – mostly weekly except for Kwekwe, where daily consumption was also higher than in any other district.

Key Messages

- The low consumption of VAM is a reflection of the low production, which was reported to be above minimal. Most households were growing biofortified crops on small pieces of land.
- Care Groups appear to be helping promote production and consumption of biofortified crops.
More households in LFSP districts had acceptable household economic access to food compared to the national level as reported by the ZimVAC 2019 Rural Assessment. However, this still constitutes less than 50% of the programme households.

This finding was despite the fact that the LFSP collected data in November 2019, towards the peak hunger season, while the ZimVAC collected data just after the harvest, in April/May 2019.

Households with a member participating in Care Groups were more likely to report increased production and consumption (75.6%) of a wide variety of foods compared to those without (62.3%).

Unavailability of food at household level was reported as one of the reasons affecting diversified consumption.

Participation in Care Groups was associated with achievement of household dietary diversity.
Summary Findings

Conclusions

- Growing small grains (sorghum and rapoko), HIB, orange fleshed sweet potato and fruits is associated with consumption of nutritionally adequate diets for women while growing of orange maize, Irish potato and orange fruits and vegetables was associated with consumption of nutritionally adequate diets for children.
- Majority of LFSP households rely on the government input distribution programme for their maize seed needs. Getting VAM and HIB into this programme would increasing production and consumption of these crops.
- Maize and green leafy vegetables were the crops reported by majority of households to be sold on local markets. It can be concluded that local markets are not a major source of nutritious food crops like orange fleshed fruits and vegetables, small grains and biofortified crops like VAM and HIB. Farmers rely mostly on what they produce for consumption.
- Small livestock production, particularly goats, indigenous and Boshveld chickens and rabbits was associated with consumption of nutritionally adequate diets for women and children.
- Knowledge on biofortified crops – what they are and their benefits is very high, but production remains minimal with heavy reliance on the programme. Unavailability of seed at the right time was reported as one major gap.
- Participation in Care Groups was associated with an adequate household dietary diversity score, increased knowledge, production and consumption for biofortified crops and adequate MDD for children.
- There remains a gap between knowledge and practice of LFSP promoted behaviour, focusing on identified barriers.
- The LFSP is doing well in MDD and HDDS compared to children and household in other areas as reported by national assessments, but poorly for MDD-W.

Recommendations / Way Forward

Diversified Crop and Livestock Production

- Support households to produce crops like small grains, VAM, HIB, orange fleshed sweet potatoes, orange fruits and vegetables and other sweet potatoes which have been shown to improve the diets of women and children.
- Support households to produce small livestock like goats, indigenous and Boshveld chickens and rabbits which have proven essential to improve the diets of women and children.

Biofortification Promotion

- Address timely availability and access of seed to farmers, as this is a major hindrance to increasing production.
- Consider getting VAM and HIB in the government input programmes as this is a major source of seed for majority of farmers, especially maize.

Nutrition Behaviour Change Communication

- Increase the coverage and reach by Care Groups in all districts, especially in EXTRA, to a minimum 80% of all eligible women and children.
- Target men, elderly women and other significant others in messages promoted through Care Groups to increase adoption.
- Focus on the highlighted barriers to adoption of promoted behaviours in running Care Groups so as to increase practice.
